Blazar Population

- ❖ The more luminous blazars have a IC peak at $\ll 100$ MeV
- ❖ We refer to these class as MeV blazars

MeV Blazars

Paliya+17

- ❖ Among most powerful persistent objects in the Universe
- ❖ Large jet power, easily larger than accretion luminosity
 - ❖ BH spin may be important
- ❖ Host massive black holes, near 1 billion solar masses (or more)
- ❖ They are detected up to very high redshift (Ajello et al. 2009)

This population is not well understood, yet very important

Favorable selection effect

High-redshift blazars preferentially host massive black holes

Black hole growth

Evolution of MeV blazars

- ❖ Evolution of MeV blazars is stronger than any other source class: i.e. their maximum density may be very early on

Clear that the radio-loud phase may play a very important role in the growing of massive black holes

Constraining the number density of extremely massive black holes in radio-loud systems is the easiest with blazars (via $2\Gamma^2$ correction)

What can they tell us ?

- ❖ The shape of the hard X-ray spectrum constrains the bulk Lorentz factor and the viewing angle of the jet
- ❖ *NuSTAR* has helped in finding a few of them
- ❖ More the number of blazars hosting massive black holes beyond $z=4-5$, more problems for BH formation theories :)

Sbarrato+, 2013, ApJ, 777, 143

High-redshift blazars can pinpoint to BH formation mechanisms

Where is the Blazar Zone?

- ❖ Lack of strong absorption, in the LAT energy range, due to UV BLR photons, places the emission region beyond the BLR (Costamante+18)

Emission Region

- ❖ Peak location and variability timescale will pinpoint the location of the emission region (BLR vs Torus)

MeV Background

- ❖ MeV blazars may be responsible for the MeV background (Ajello+09)
However see Inoue, Ruiz-LaPuente etc

Current Status

- ❖ MeV blazars are hard to detect despite being bright !
 - ❖ lack of an MeV mission
- ❖ Bright in X-rays
 - ❖ tens detected by *Swift*/BAT (Ajello +09)
 - ❖ a few discovered (via follow up) with NuSTAR (Ghisellini, Sbarrato etc)

Current Status

- ❖ MeV blazars are hard to detect despite being bright !
 - ❖ lack of an MeV mission
- ❖ Bright in X-rays
 - ❖ tens detected by *Swift*/BAT (Ajello +09)
 - ❖ a few discovered (via follow up) with NuSTAR (Ghisellini, Sbarrato etc), Fermi-LAT (Ackermann+17)

Oh, Koss et al. 2018 (BAT 105m)

Prospects of detection with AMEGO

How many MeV blazars can be detected ?

- ❖ >100 blazars at $z>3$

two extrapolations of
blazar LF from Swift/BAT
(Ajello et al. 2009)

| z | $N(>z)$ | $N(>z)$ |
|-----|---------|---------|
| 3 | 199 | 102 |
| 4 | 154 | 57 |
| 5 | 76 | 5 |
| 6 | 24 | 0 |
| 7 | 9 | 0 |
| 8 | 3 | 0 |

PLE Evolution (A09)
up to high z .

PLE Evolution (A09) to $z \sim 4$
+ high z exponential cut-
off at $z > 4$.

Summary

- ❖ An MeV mission (like AMEGO) may detect hundreds of MeV blazars up to $z \sim 5$ and maybe beyond
- ❖ SMBH growth
- ❖ Disk-jet connection
- ❖ Location of emission region and emission mechanism (EC-BLR/Torus)
- ❖ MeV background

How to grow quickly a black hole

Credit: HST image

Simulation by
A. Sadowski

S. Bonoli, 2011

What can they tell us ?

- ❖ 10^5 black hole formation from the collapse of a massive turbulent disk produced by a merger (Mayer+10, Nature)

What can they tell us ?

- ❖ 10^5 black hole formation from the collapse of a massive turbulent disk produced by a merger (Mayer+10, Nature)
- ❖ Fraction of major mergers that satisfy conditions to form heavy BH seeds steadily increases from $z > 2$

MeV blazars can pinpoint to BH formation mechanisms

Recent Detections

- ❖ Improved low-energy response (with P8) allowed Fermi-LAT to detect 5 $z > 3.1$ blazars (Ackermann+17)

Recent Detections

- ❖ All are objects with $M_{\text{BH}} > 10^{8-9} M_{\text{sun}}$
- ❖ All have $\Gamma \sim 13-15$
 - ❖ every single blazars implies $2\Gamma^2$ objects pointing somewhere else !

Recent Detections

- Between redshift 3 and 4 we have 2 blazars with $M_{\text{BH}} > 10^9 M_{\odot}$
 - They account for ~ 675 more objects at the same redshift
- Only 5 system were known before
 - Brings up the space density estimate by 40% !

Recent Detections

- ❖ Despite the good news, they still remain very hard to detect in Fermi
- ❖ These objects are bright! but extremely soft, so their photons are spread everywhere
- ❖ Population of MeV blazars could be large

Favorable selection effect

γ -ray quiet are MeV blazars

high- z are MeV blazars

γ -ray undetected
